

# Reflection 9 Part 1 Video 13

Denotation:

$G = (V, E)$

$V = \{v1, v2, v3, v4\}$

$E = \{\{v1, v2\}, \{v2, v3\}, \{v3, v4\}\}$

note: use “{}” or “()” properly

**incident**  
相交

We say that *one edge* is incident to *one node*.

**deg(v) = k.** (e.g.  $\text{deg}(v1) = 2$ , meaning that node v1 is connected to 2 edges).

Definition of Graph:

**V** (vertices 顶点) or nodes

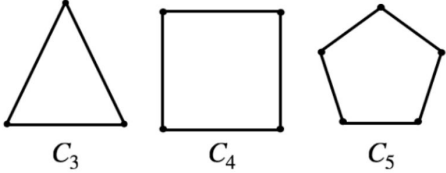

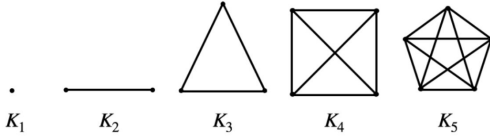

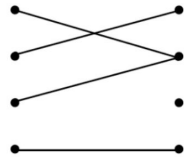

**E** (edges 边): every edge has one or two nodes connected to it.

- In normal cases, an edge is connected to 2 nodes, e.g.: 
- However, if one node is tied to itself, then there's only one node connected to the edge. e.g.: 

**degree** 度: the number of edges connected to it.

**adjacent** 相邻: two nodes connected to each other

# Three Kinds of Graphs

|                     | Examples   | Definition   | Note                 |
|---------------------|--|--|----------------------|
| Cycle Graph         |  <p style="text-align: center;"><math>C_3</math>      <math>C_4</math>      <math>C_5</math></p>   | $C_n$ has <u><math>n</math> vertices</u> ( $v_1, v_2 \dots v_n$ )<br>and <u><math>n</math> edges</u> ( $\{v_1v_2\}, \{v_2v_3\} \dots \{v_nv_1\}$ )   | $C_n$                |
| Complete Graph      |  <p style="text-align: center;"><math>K_1</math>      <math>K_2</math>      <math>K_3</math>      <math>K_4</math>      <math>K_5</math></p> | There's one edge between every pair of vertices.   | $K_n$                |
| Bipartite Graph 二分圖 |    | <ol style="list-style-type: none"> <li>every edge in the graph connects a vertex in <math>V_1</math> and a vertex in <math>V_2</math></li> <li>no edge in <math>G</math> connects either 2 vertices in <math>V_1</math> or 2 vertices in <math>V_2</math></li> </ol> | can also be complete |

## Bipartite Graph + Complete

$K_{3,2}$

$K_{3,2}$  is COMPLETE

**Question 1:** why is this graph denoted as “ $K_{3,2}$ ”? Normally there’s only one number after the “K”.

**Question 2:** this bipartite graph looks very similar to what we learned in functions (onto, bijection, etc.) . In what cases should we use functions or bipartite graphs to model a problem?

# Handshake Theorem

If we sum up  $\deg(v_1)$ ,  $\deg(v_2)$ , ..., until  $\deg(v_n)$ , then we have to divide the result by 2. This is because we've counted every edge twice.

## Handshaking Theorem

Let  $G = (V, E)$  be a graph.  $2|E| = \sum_{v \in V} \deg(v)$

# Isomorphism 同构

## Isomorphism

Graphs  $G$  and  $H$  are isomorphic if there is a bijection  $f$  from  $V$  the vertex set of  $G$  to  $W$  the vertex set of  $H$ , such that if  $(a,b)$  is an edge in  $G$  then  $(f(a),f(b))$  is an edge in  $H$ , for all edges

It's like twisting some molecules in the space. The shape changes but the structure stays the same.

Subgraph: a tool to examine if two graphs are isomorphic

$G_1$  and  $G_2$  are not isomorphic if  $H$  is a subgraph of  $G_2$  but not a subgraph of  $G_1$ .

# Perfect Matching

## Perfect Matching

A perfect matching of a graph is a set of edges such that every node is associated with exactly one of these edges

Looking for a set of edges that can form a **bijection** from vertices set A to vertices set B?

## video 14: tree

- Tree: an undirected graph with a root
- Root: every node is connected to it by exactly one path
- Parent and Child
- Leaf and Internal Node: has no children vs. has child(ren)
- Levels and Height (starts from 0)
- Subtree: pick a node X to be the root
- Binary tree: each node has **at most 2** children
- M-ary tree: each node has **at most m** children
- Full: each node either has **0 or m** children
- Complete: **m-ary tree** with all leaves that are the **same height**
